Comparison of cloud base heights

*Ulrich Görsdorf, Gregor Pittke, Neda Boyouk
Deutscher Wetterdienst, Meteorologisches
Observatorium Lindenberg*

Cloud base height and cloud cover are important for

- Weather reports on airports (METAR, SPECI, ..)
- Aviation forecast for aircrafts which needs visual flight conditions (rescue helicopters, ...)

required accuracy < 30 m

Big challenge for the future, because of the automation of weather stations

- Automation of all 183 weather stations of DWD until 2021
- Automatic generation of airport reports (METAR) until 2021

What do we want to know from such comparison?

For different clouds- and weather conditions, especially for very low clouds:

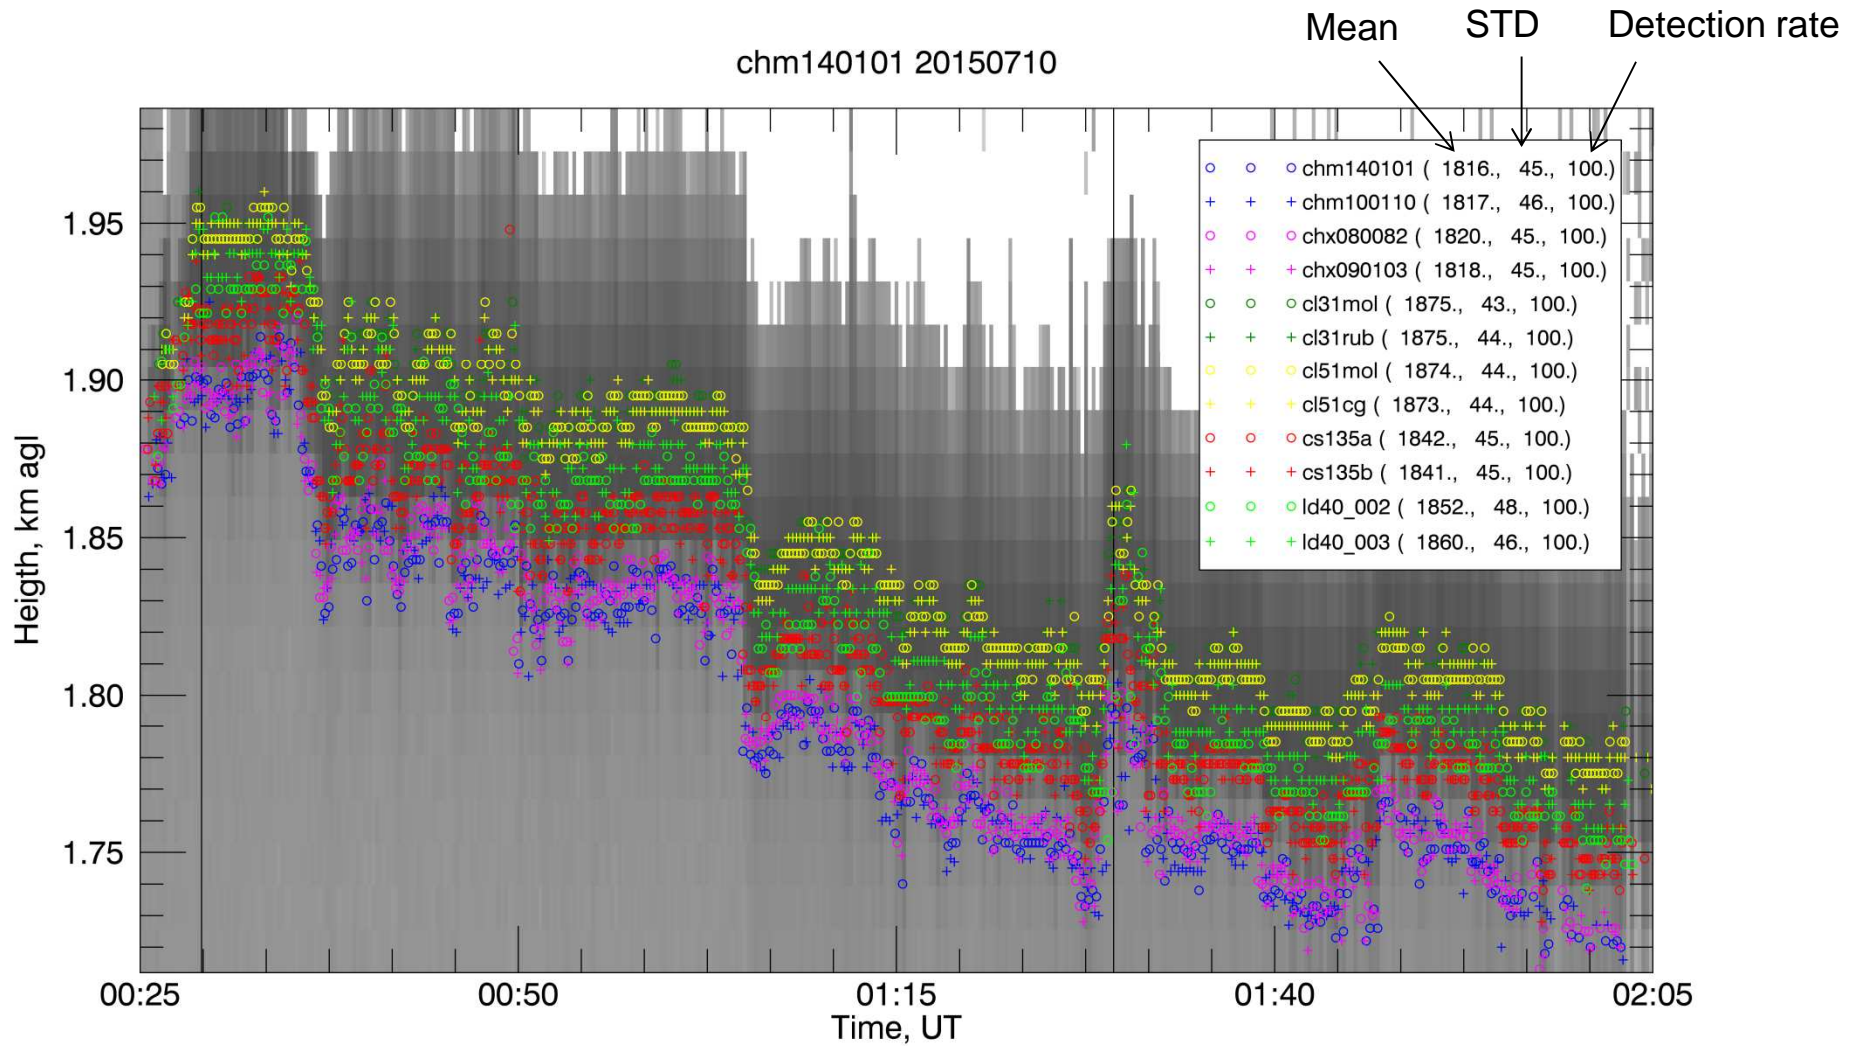

1. Detection rate, false alarm rate of different systems
2. Cloud base height differences
3. Repeatability (comparisons of the same instrument type)
4. Differences in backscatter profiles (especially at lowest heights)

Difficulties:

1. No independent reference providing information of cloud occurrence and cloud base height
2. No general definition of cloud and cloud base height

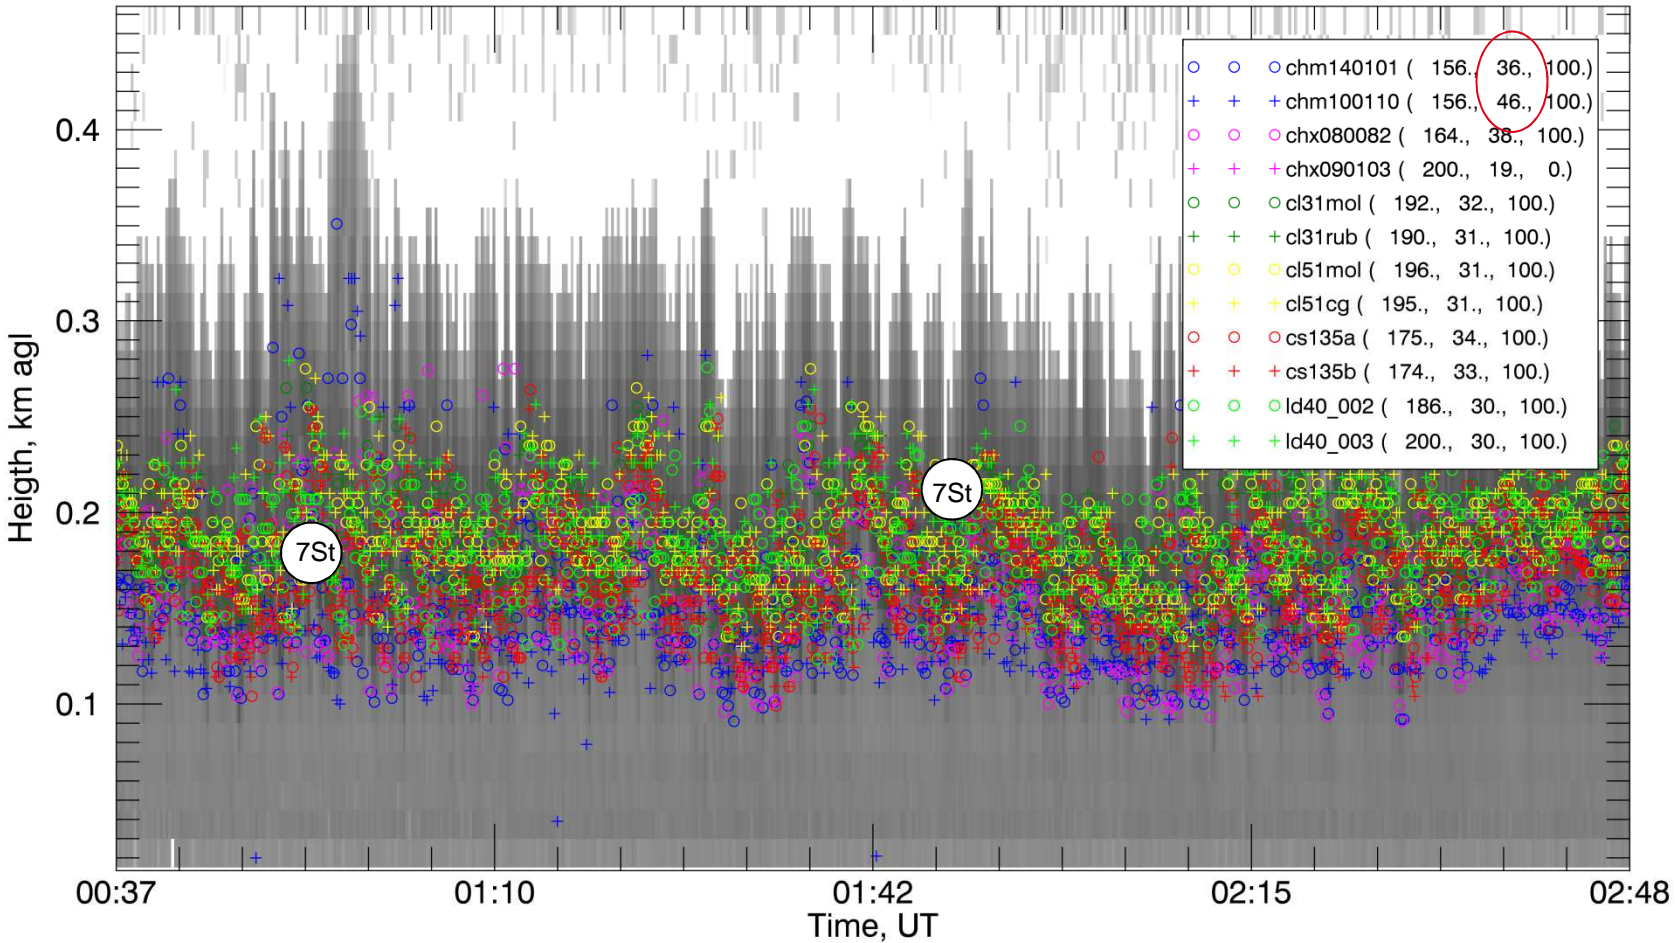

Sc without drizzle/rain

Low St without rain

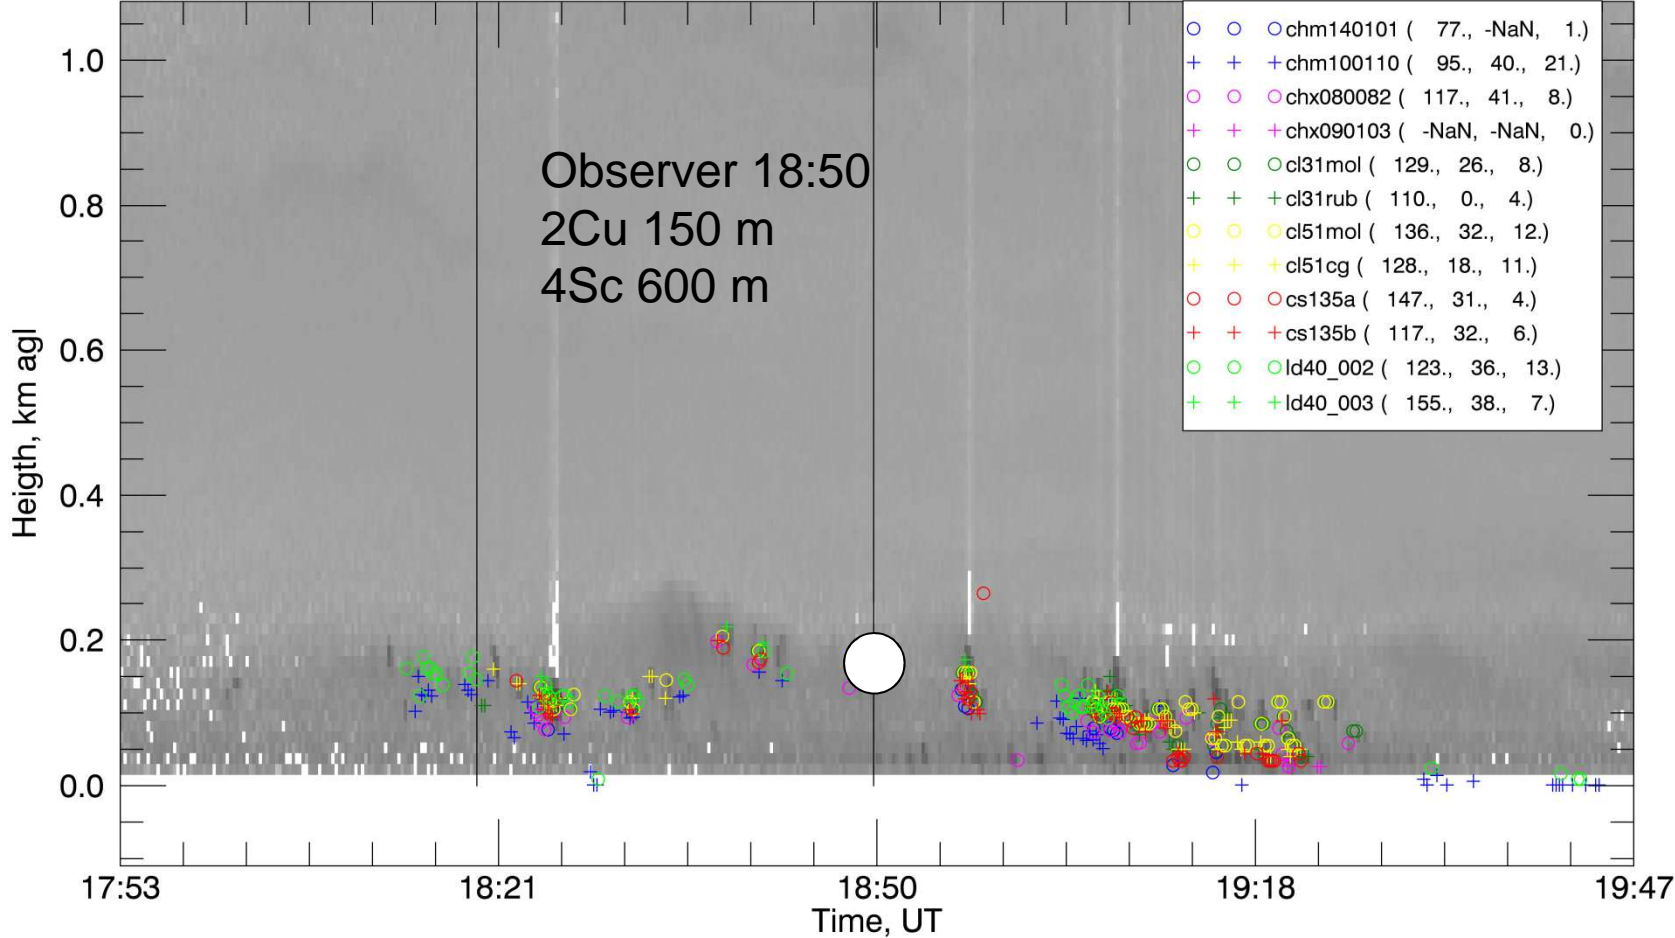

chm140101 20150628

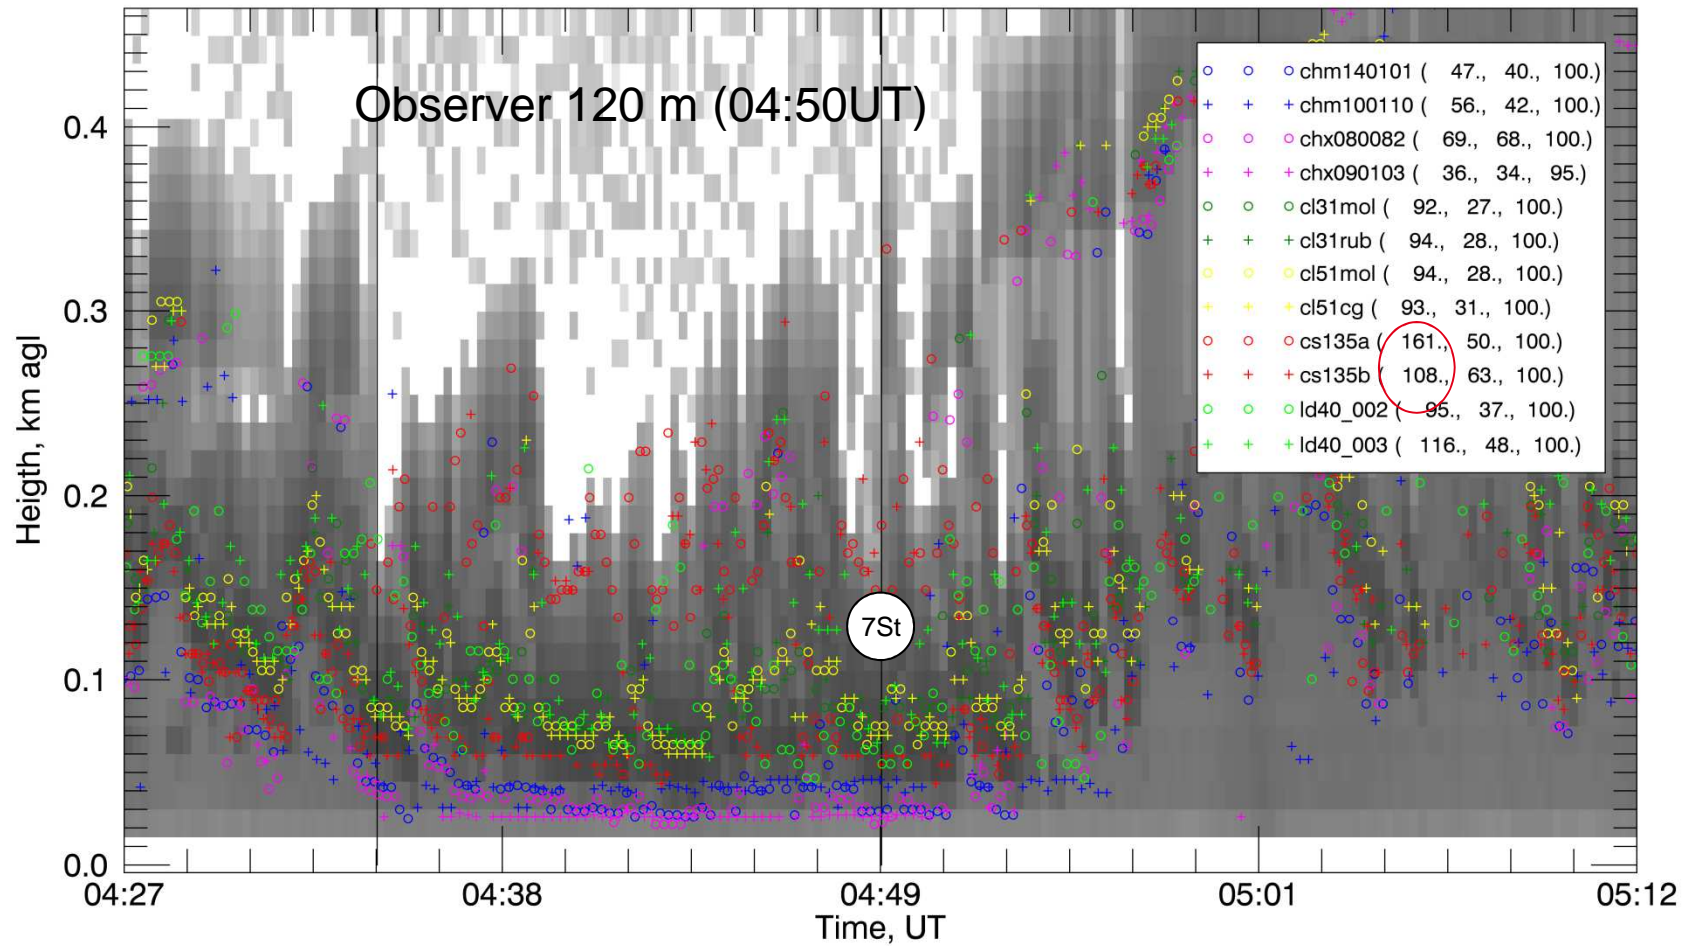

Low Cu without rain

chm140101 20150714

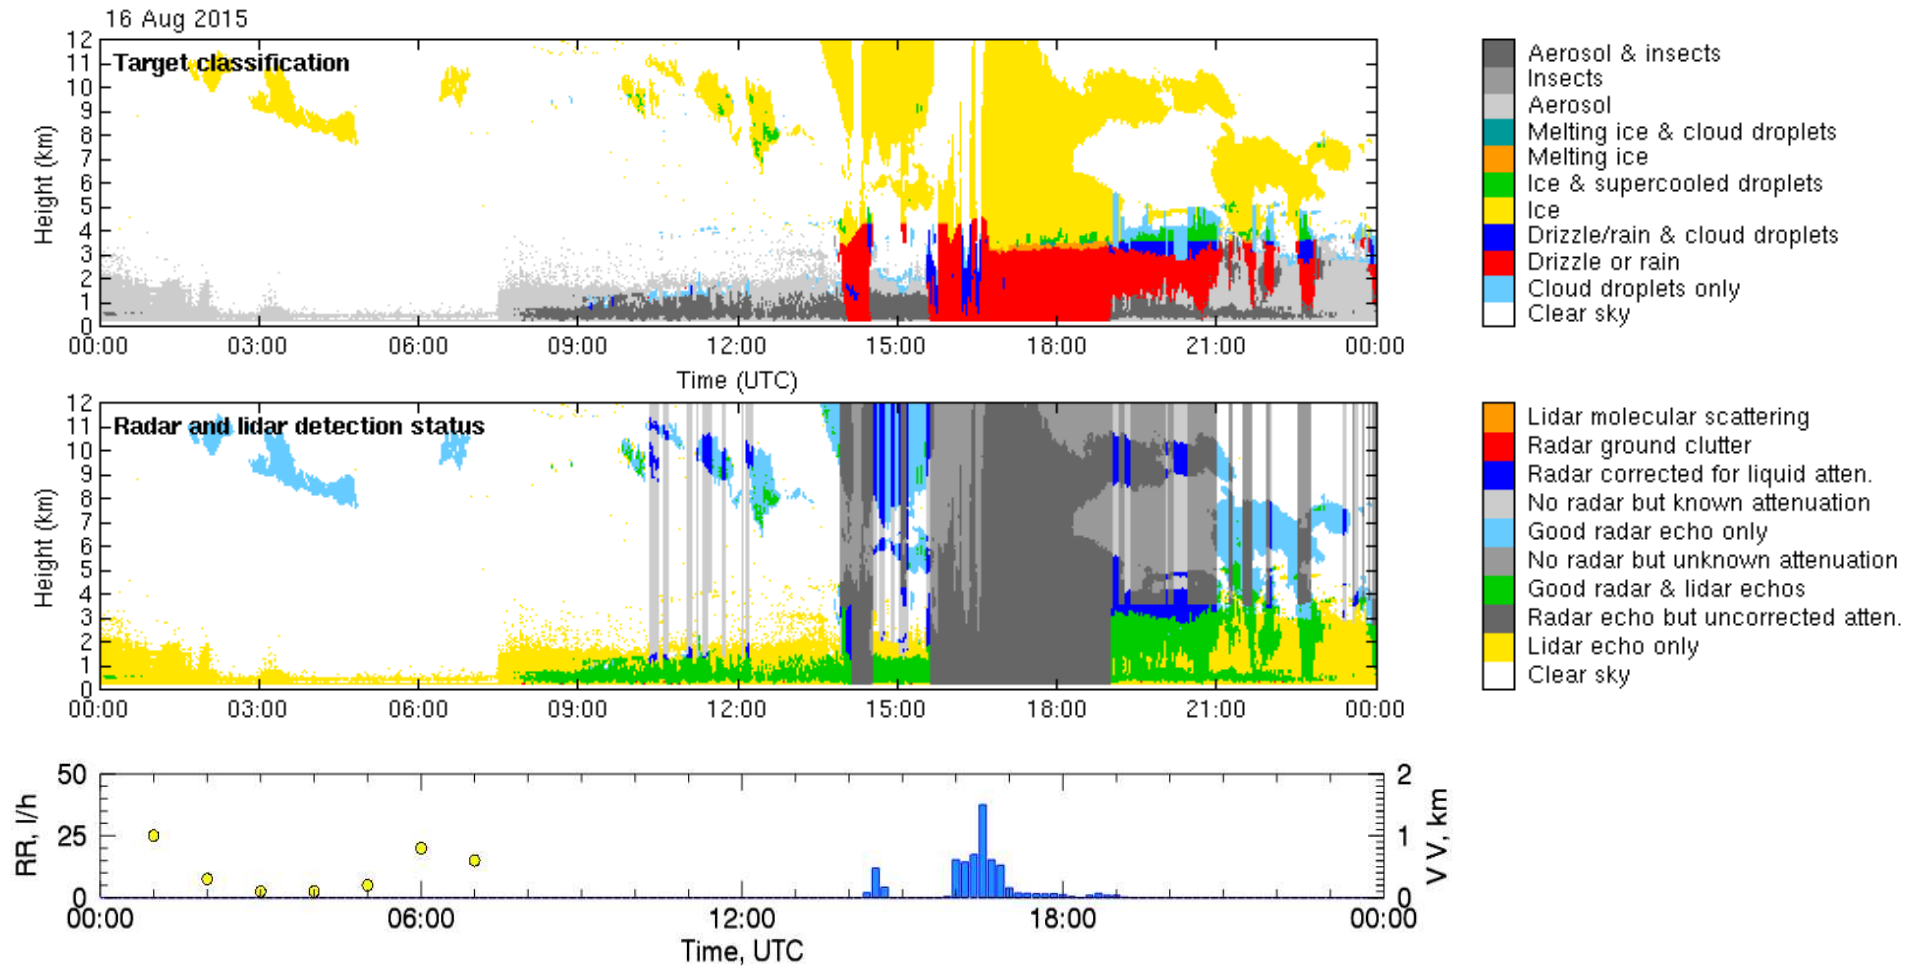

Low St with rain

chm140101 20150828

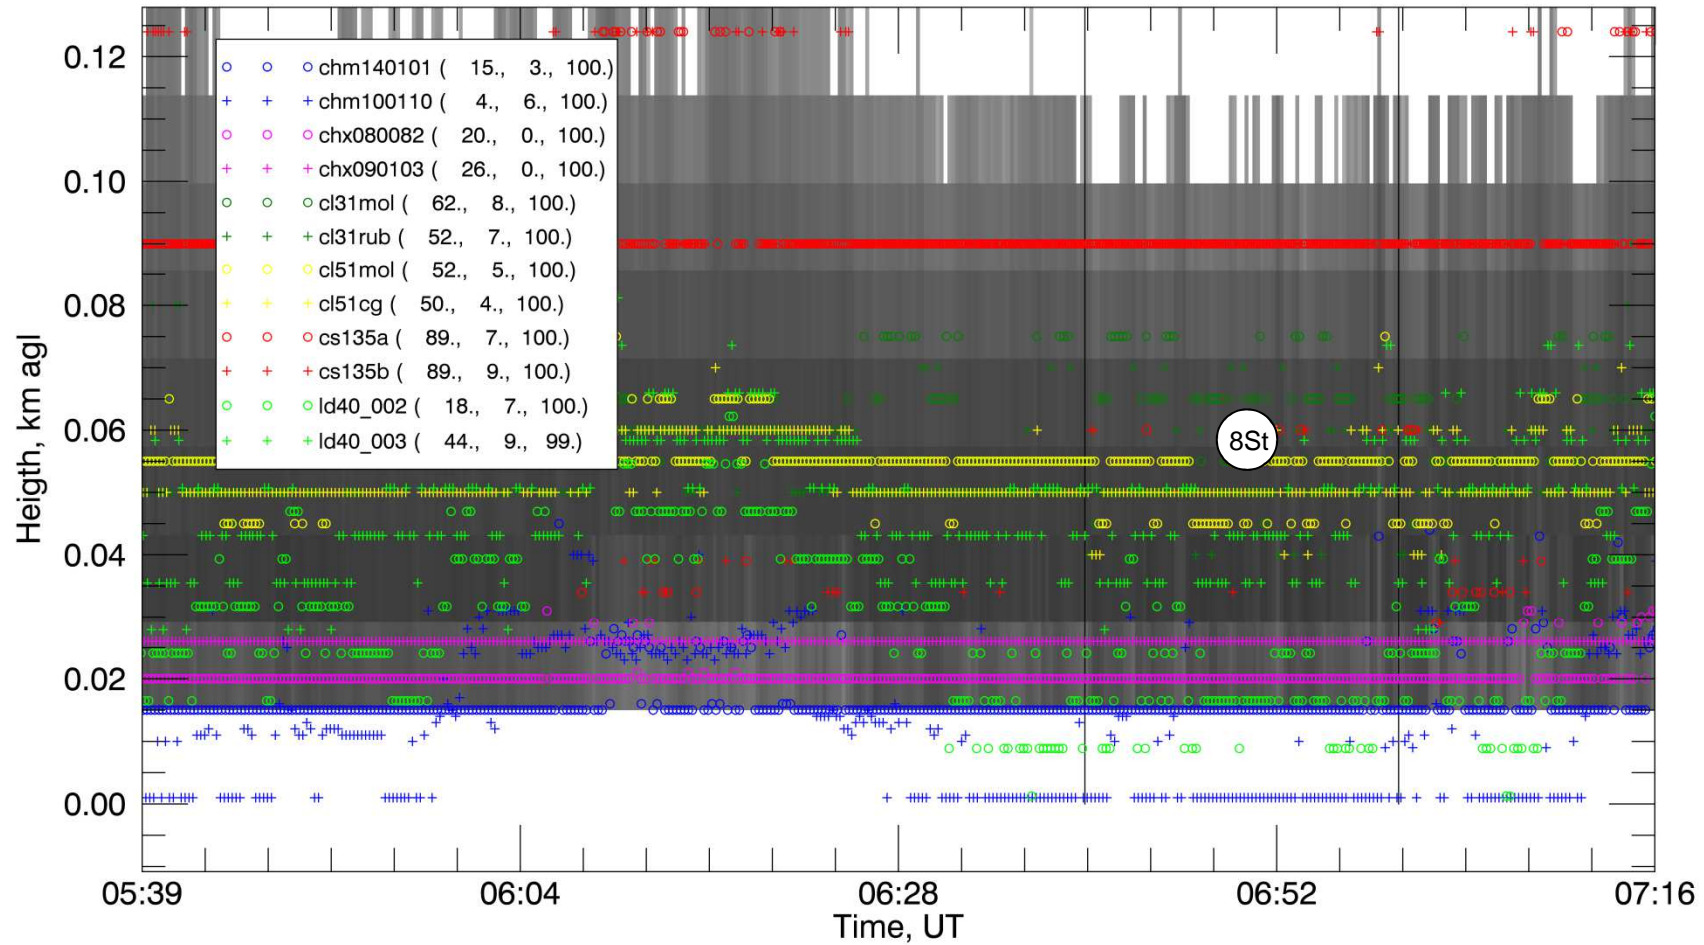

Fog dissipation, Cu hum, Cb heavy rain, moderate rain/virga

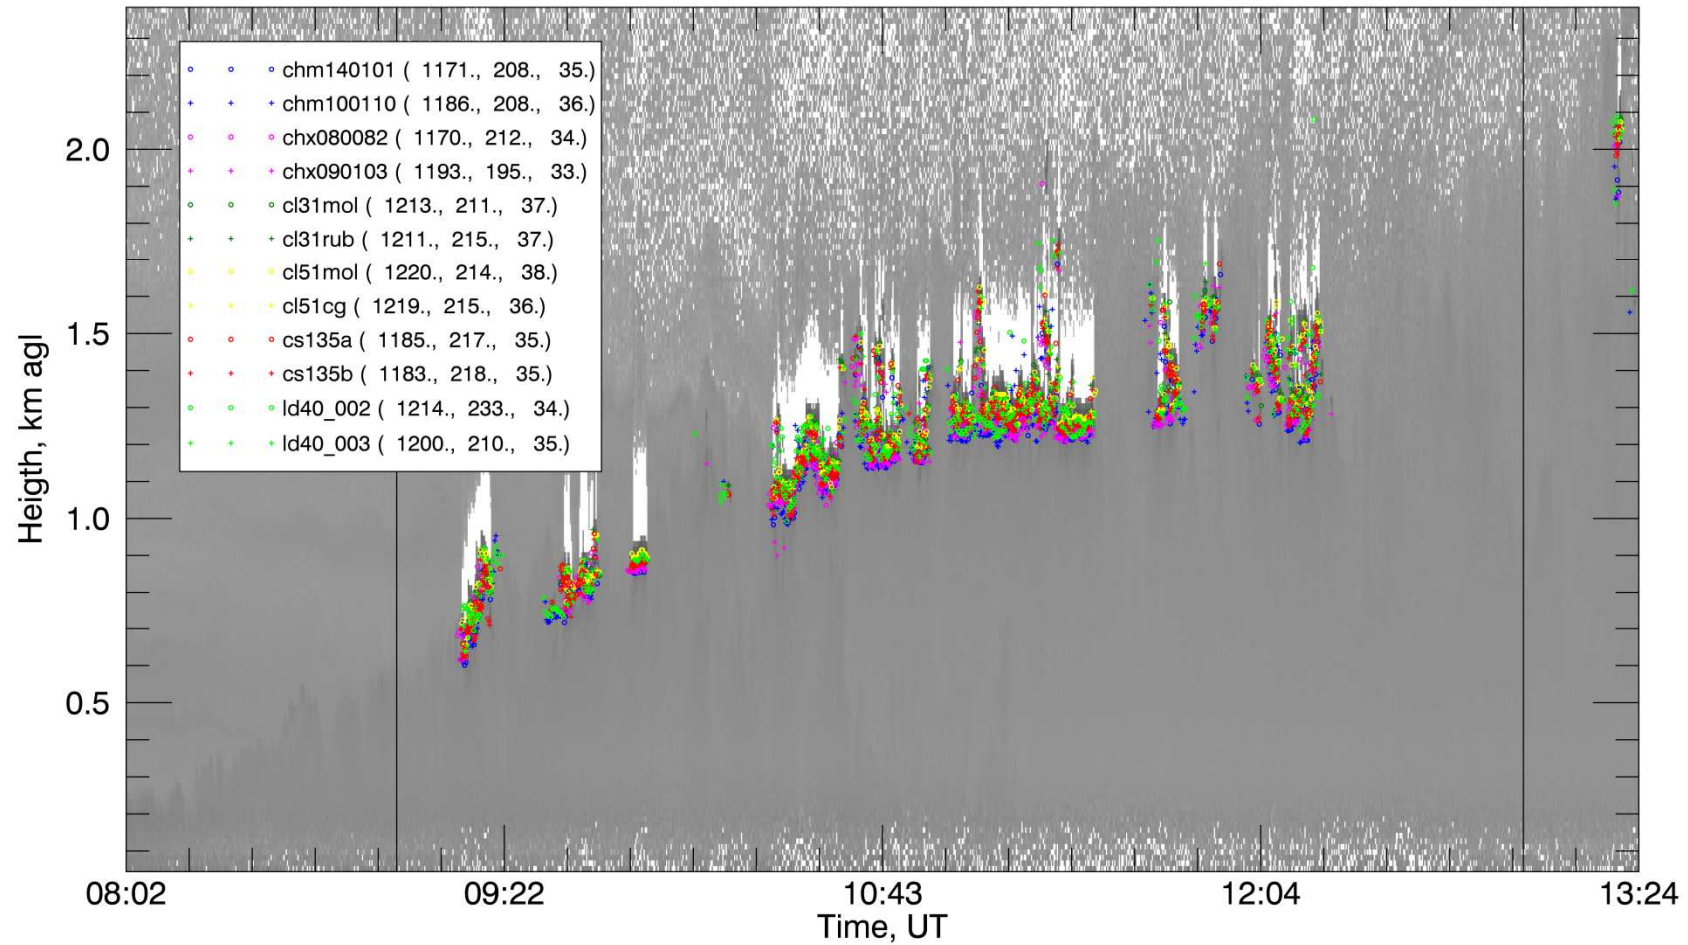

Fog dissipation

chm140101 20150816

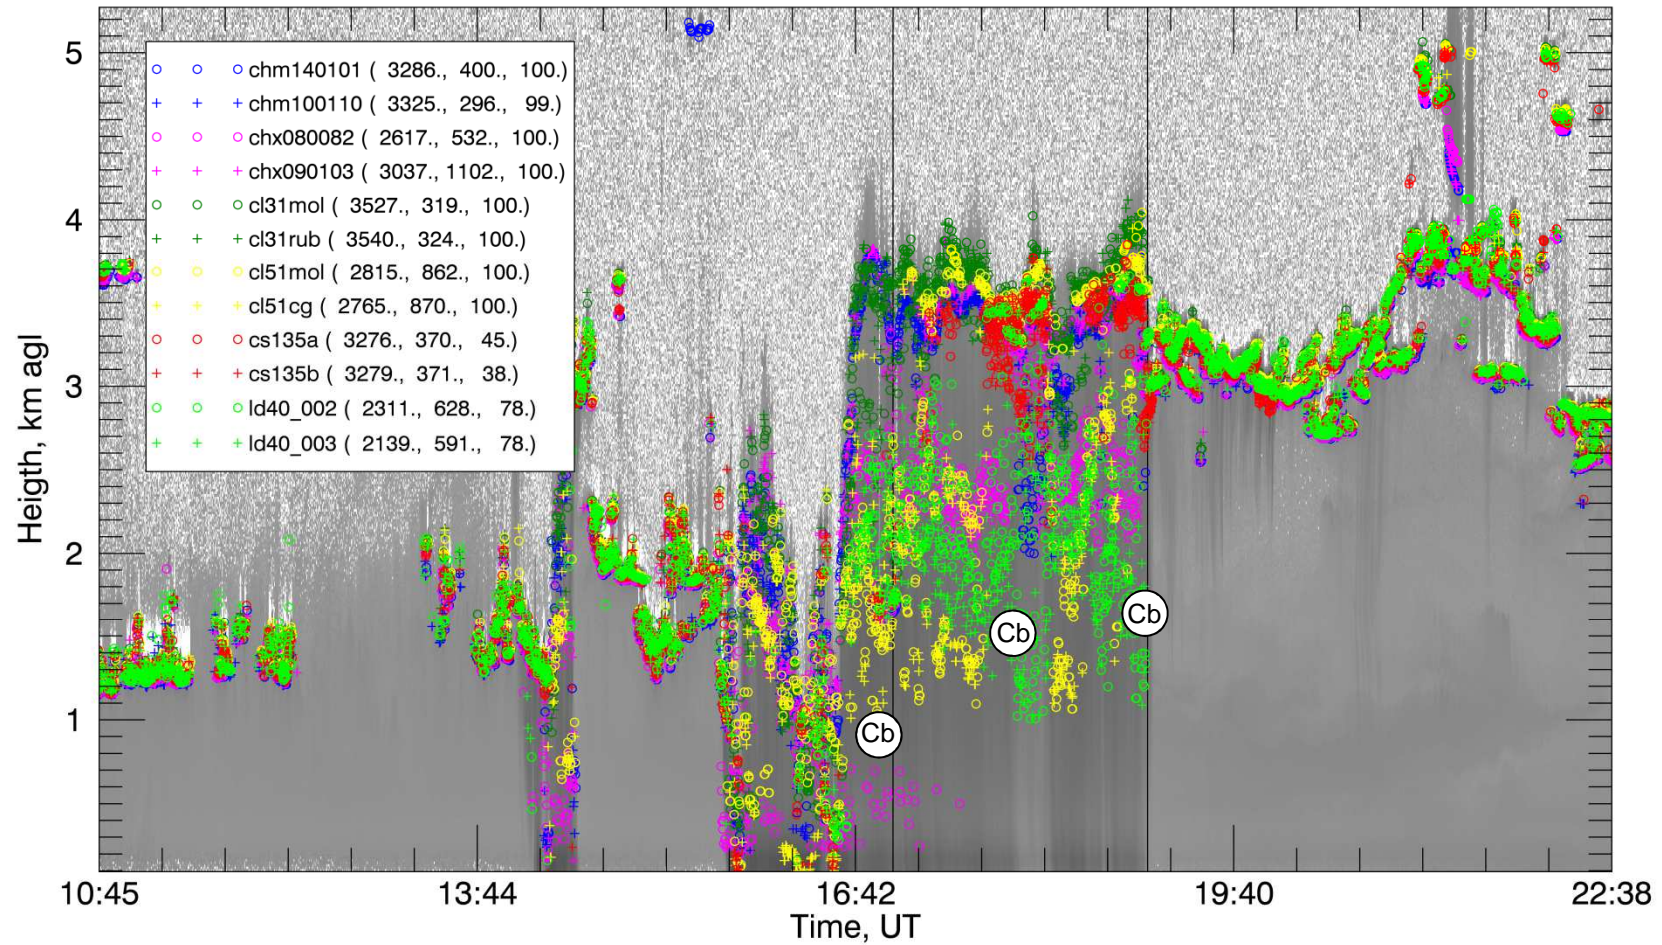

2-4 Cu hum/med

chm140101 20150816

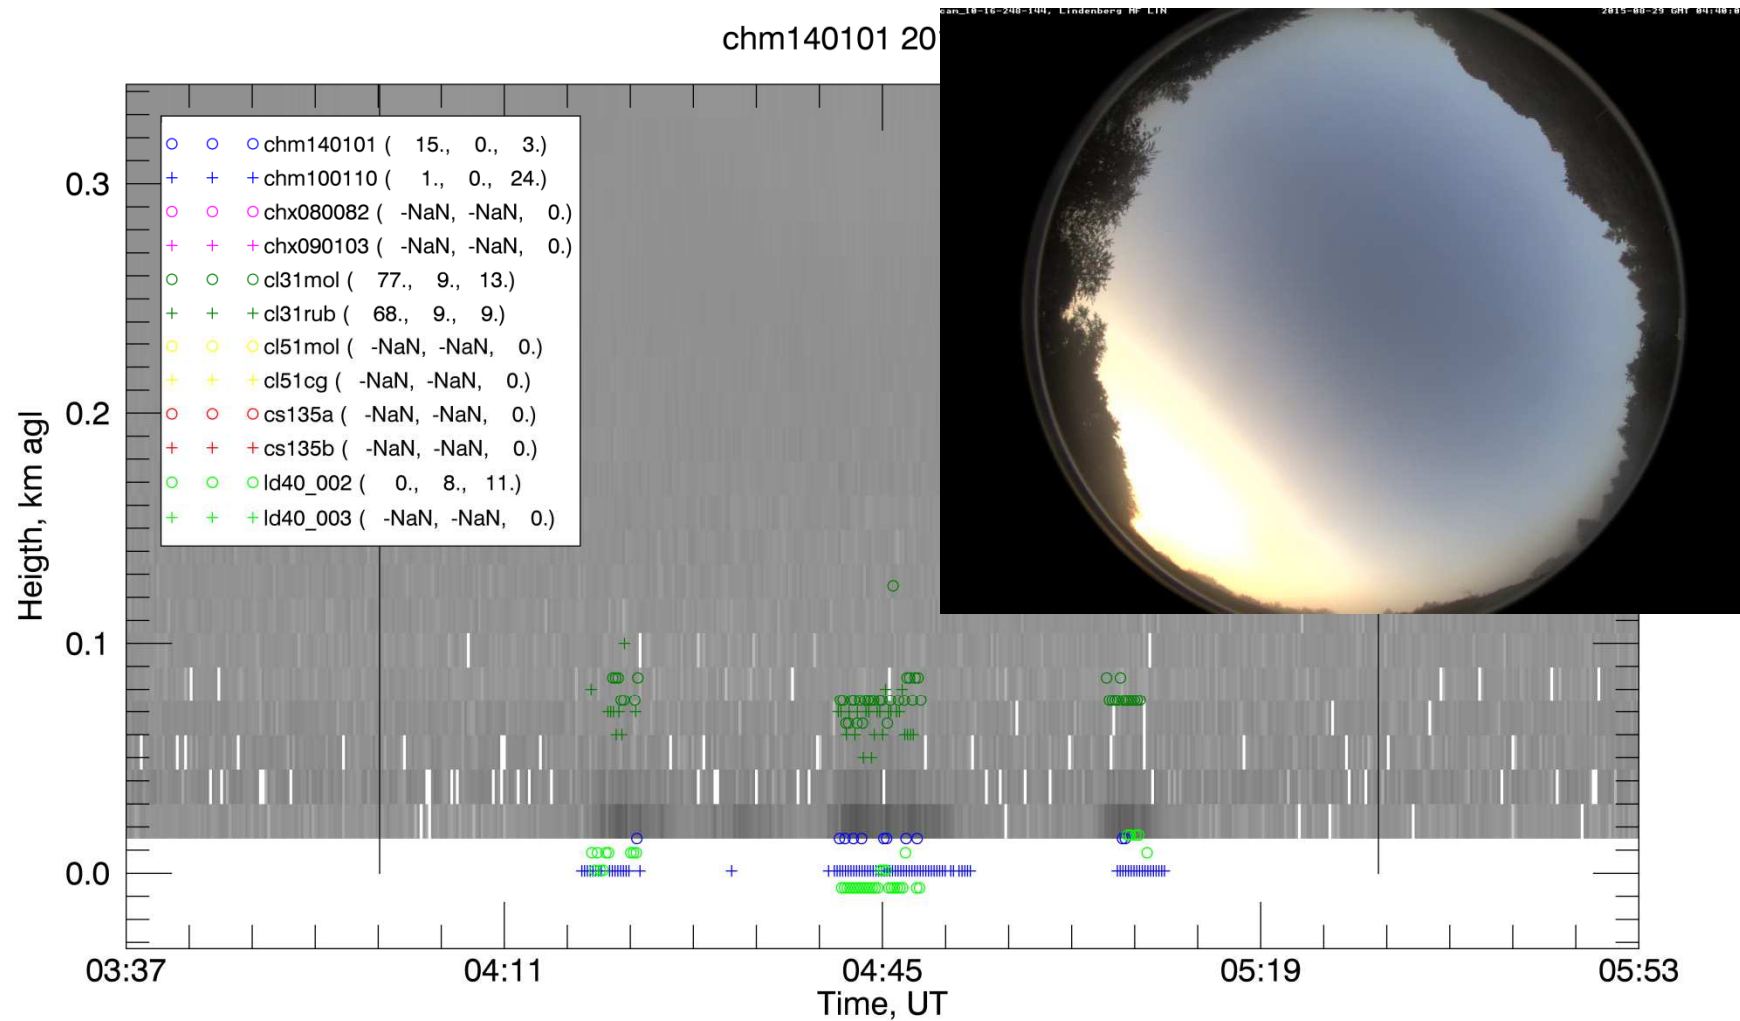

Cb with rain

chm140101 20150816

Erroneous detection of low clouds

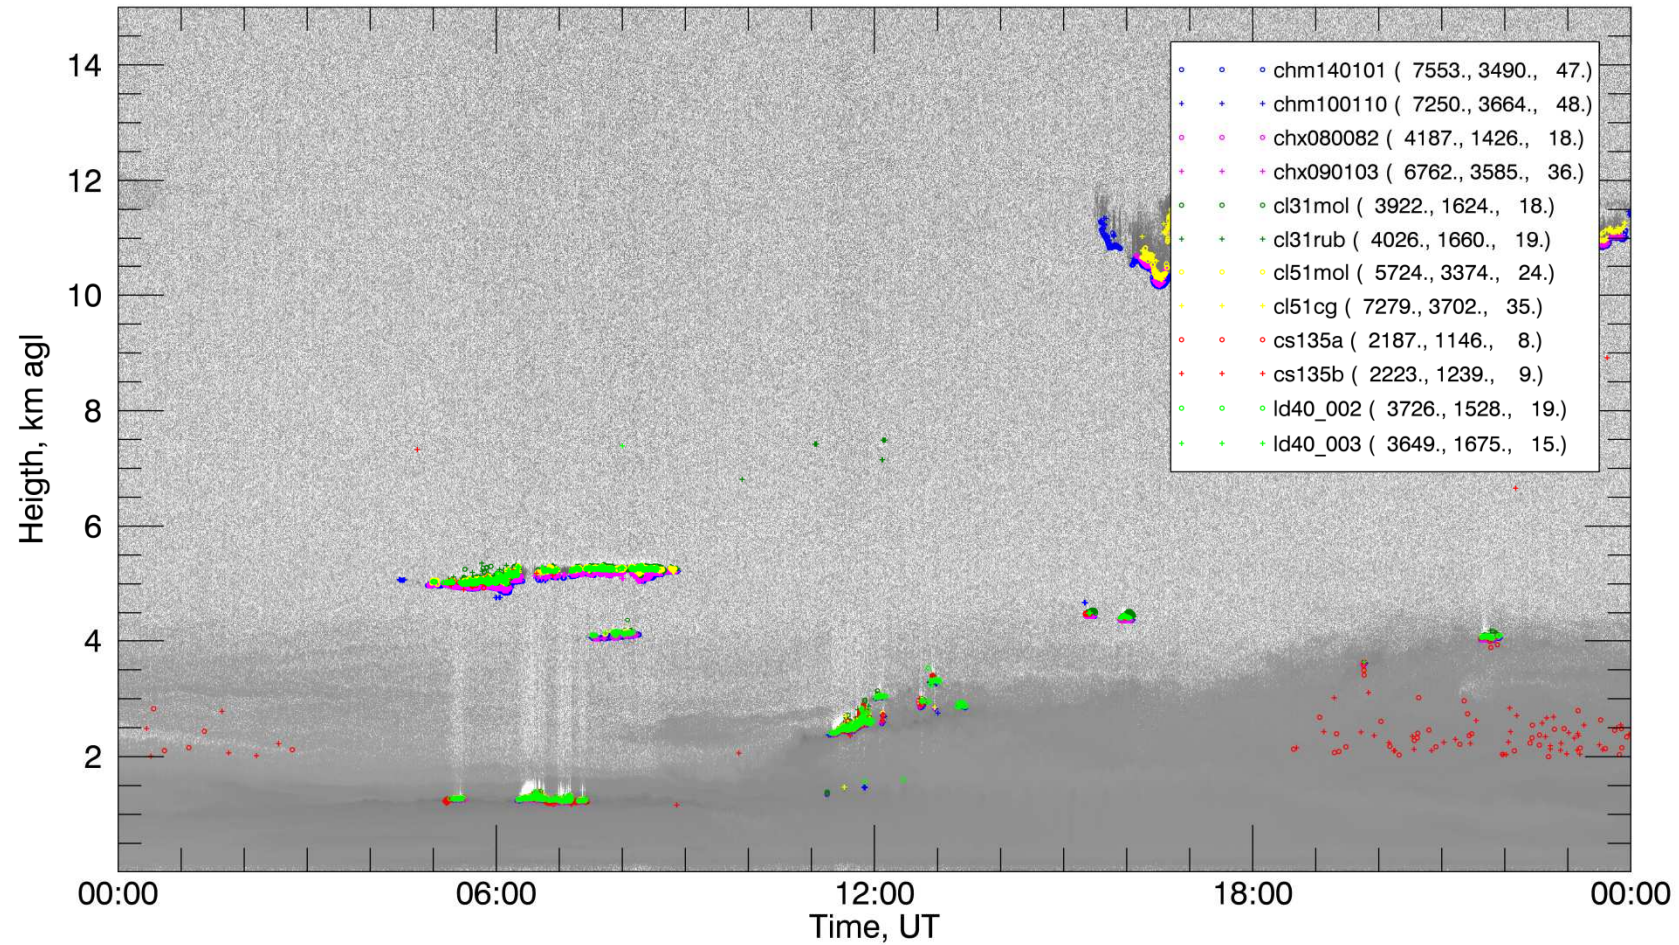

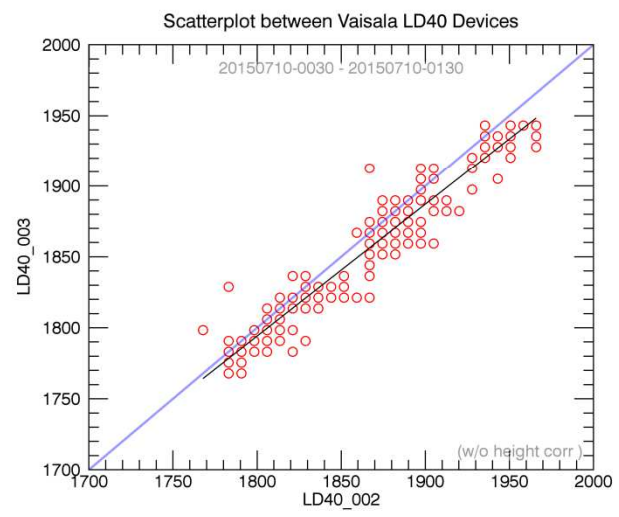

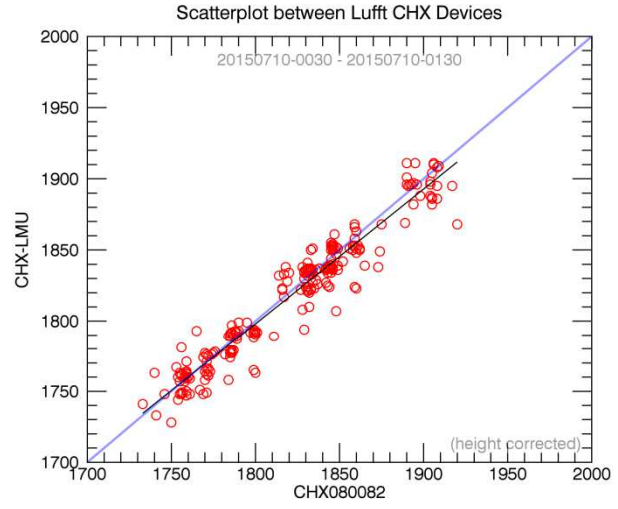

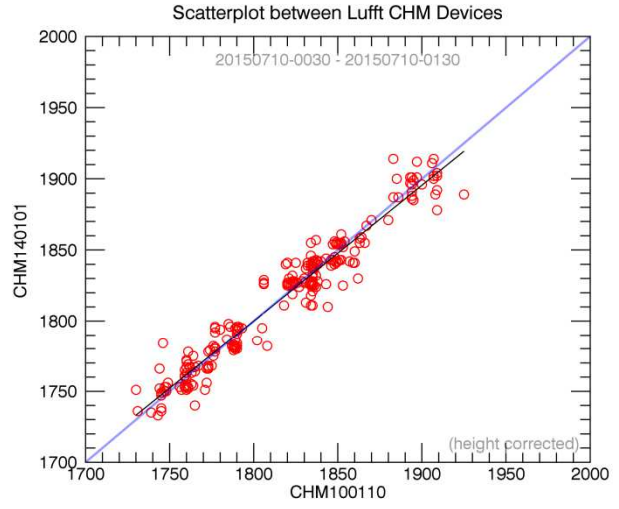

chm140101 20150830

Erroneous cloud detection by CS135

chm140101 20150810

Summary (preliminary)

- For well defined water clouds
 - the detection rate of all systems is similar (except CHX-LMU)
 - there are systematic differences of cloud base heights, cloud base heights of LUFFT systems are about 30 .. 60 m lower than cloud base heights of Vaisala systems CL31, CL51; LD40 and Campbell systems represent the average
- Similar results for very low clouds (overcast), but differences in detection rate for scattered clouds
- In situations of very wet boundary layer CHM's and CL31's tend to detect erroneously clouds
- In rain very large cloud base differences between the system
- During fog dissipation cl31,51 show the most realistic values, Campbells cloud base heights look artificial
- Campbell ceilometers tend to analyse aerosol layers as clouds (during night)

Summary, cloud base differences

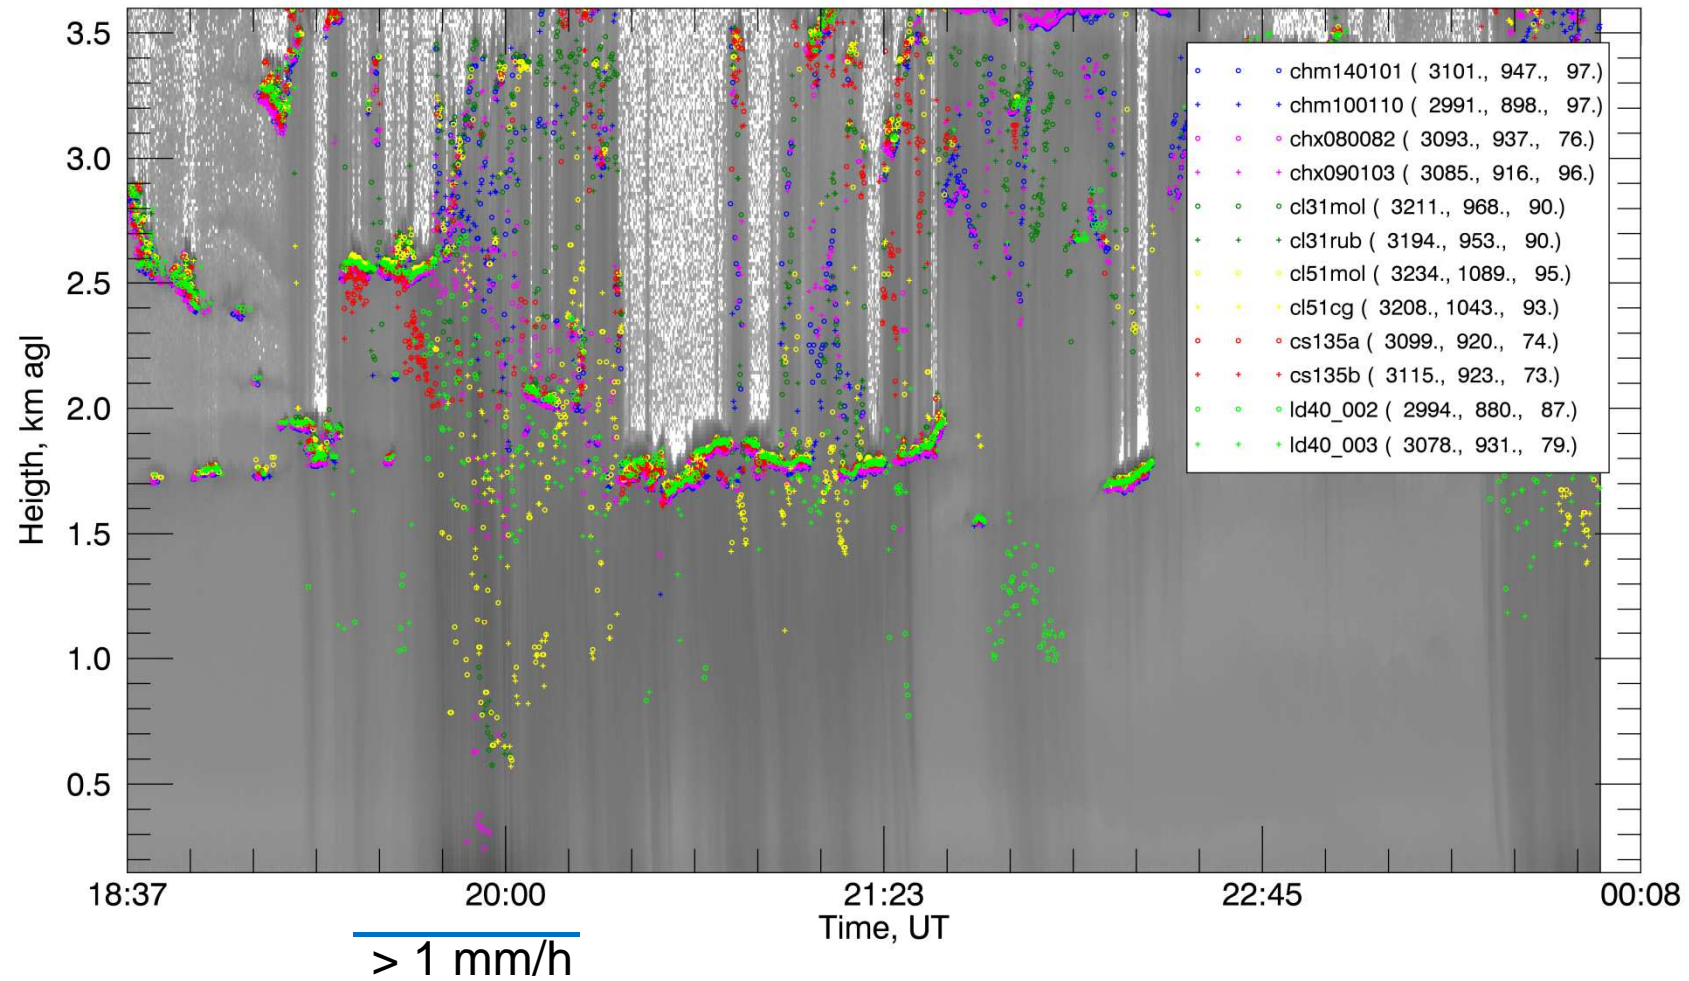

System	Sc without rain (1852)	Low St without rain	Fog dissipation	Cb with moderate rain
Mean	1852	178	48	2998
CHM140101	-36	-28	-33	288
CHM100110	-35	-28	-45	326
CHX080082	-31	-19	-28	-380
CHX090103	-33	-	-22	40
CL31MOL	24	7	14	530
CL31RUB	24	4	4	543
CL51MOL	23	10	4	-183
CL51CG	22	9	2	-233
CS135a	-10	-11	41	279
CS135b	-11	-13	41	281
LD40_002	0	3	-30	-687
LD40_003	8	15	-4	-859

Categorization of cloud and weather conditions

1. Stratocumulus without drizzle or rain, 7-8 Sc
2. Stratocumulus with drizzle (virga), 7-8 Sc virga
3. Stratocumulus with rain, 7-8 Sc rain
4. Cumulonimbus/Nimbostratus/Stratus with rain, 7-8Cb/Ns/St rain
5. Low Stratus without rain, $vv > 1$ km
6. Low Stratus with rain, $vv < 1$ km
7. Cumulus hum/med, 3-7 Cu
8. Fog, $vv < 500$ m, sky not visible, fog dissipation
9. Cirrus, 7-8Ci
